TEMASEK JUNIOR COLLEGE PRELIMINARY EXAMINATION
H2 GEOGRAPHY (PAPER 1) SUGGESTED ANSWER SCHEME

1 (a) Possible responses include: [4]

- Improvement in SDG Performance
- Unevenness observed in progress
- Group response based on the various pillars of sustainable development
- Analyse based on categories provided in the resource

(b) Possible responses include: [6]

Sustainable Development Goal 9 (SDG 9) aims to build resilient infrastructure, promote inclusive and sustainable industrialization, and foster innovation. For India, a country with ambitious industrial growth targets and rapid urbanization, progress towards SDG 9 has been a critical component of its broader development agenda. However, the COVID-19 pandemic, which struck in early 2020, posed unprecedented challenges that significantly disrupted India's trajectory on this goal, revealing vulnerabilities across industry, infrastructure, and innovation sectors.

India's industrial sector, a vital engine for economic growth and employment, suffered a severe setback due to the pandemic. The nationwide lockdowns imposed in March 2020 led to the abrupt closure of factories, manufacturing plants, and construction sites. Supply chains, both domestic and international, were disrupted, causing shortages of raw materials and delaying production. This industrial halt led to a sharp contraction in manufacturing output, with key sectors like textiles, automobiles, and electronics particularly affected. Small and medium enterprises (SMEs), which form the backbone of India's industrial landscape, were disproportionately impacted due to limited financial buffers and reduced market demand. The resulting job losses and reduced incomes had cascading effects on consumer spending and investment in industry.

Infrastructure development is crucial for supporting industrialization and innovation. The pandemic severely impacted ongoing infrastructure projects across the country. Restrictions on movement and labor shortages delayed construction activities for roads, railways, ports, and energy projects. Financial constraints also emerged as government revenues declined and private sector investments slowed. This funding squeeze led to project delays and, in some cases, cancellations. Additionally, disruptions in logistics and transport networks affected the movement of goods and materials, further hindering infrastructure efficiency. The lack of robust digital infrastructure in many regions exacerbated these challenges, as remote monitoring and management systems were not widely available.

The impacts of COVID-19 on SDG 9 were unevenly distributed across regions and social groups. Industrial hubs in urban centres suffered differently than rural areas where informal industries predominate. Workers in informal and unorganized sectors, many without social security or healthcare, faced severe hardship, impacting labour availability and industrial productivity. Regional disparities in infrastructure quality became more apparent, with less-developed states struggling more to maintain industrial and infrastructural activities. This uneven impact risked

[not for reproduce without authorisation from Temasek Junior College]

widening existing inequalities in access to industrial opportunities and infrastructure services.

(c) Possible responses include: [5]

Economic sustainability is a key dimension of sustainable development, emphasizing the need for economic growth that can be maintained over the long term without causing severe environmental degradation or social inequality. It involves the efficient use of resources, creation of employment, reduction of poverty, and building resilient economies that can support current and future generations. For countries with fast-growing populations, the task of measuring progress towards economic sustainability is particularly challenging due to different factors.

Countries experiencing rapid population growth face significant demographic pressures. High birth rates, youthful age structures, and large cohorts entering the workforce intensify demands for jobs, infrastructure, education, healthcare, and basic services. These pressures complicate the measurement of economic sustainability for several reasons. In countries with rapidly expanding populations, overall GDP may grow significantly, but GDP per capita may stagnate or even decline if population growth outpaces economic growth. This disparity makes it difficult to judge whether economic development is truly sustainable in terms of improving individual living standards. Furthermore, fast population growth increases the labor supply substantially. Economic sustainability requires that enough productive employment opportunities be created to absorb new entrants into the job market. Measuring this is complex because official unemployment figures may not capture underemployment, informal work, or precarious jobs, which are widespread in many fast-growing countries. Additionally, rapid population growth intensifies demand for natural resources such as water, energy, and land, as well as public services. Economic growth may appear robust, but if it comes at the expense of resource depletion or declining quality of life, sustainability is undermined. Capturing this balance quantitatively is difficult, as traditional economic indicators often exclude environmental or social costs.

To address these difficulties, countries need to invest in strengthening statistical systems, expanding the scope of indicators to include environmental and social dimensions, and enhancing data disaggregation to reflect regional and demographic disparities. Integrating technological innovations such as satellite data, big data analytics, and mobile surveys can improve data collection and analysis. Moreover, fostering inclusive economic growth that generates decent jobs, protects the environment, and reduces inequalities will require coordinated policy efforts and international cooperation. Only by developing more comprehensive and context-sensitive measurement frameworks can fast-growing countries accurately assess their progress and chart effective pathways toward genuine economic sustainability.

(d) Possible responses include: [5]

- Shared or unique trading partners
- Value of import and export from trade partners
- Evenness of share
- Trade balance

(e) Possible responses to consider: [5]

Input Stage
The input stage involves the sourcing of raw materials, components, and intermediate goods required for production. In GPNs, TNCs procure these inputs from various locations worldwide, depending on where resources are abundant, cheap, or of high quality. For example, a smartphone manufacturer may source rare earth metals from one country, electronic components from another, and plastics from yet another. Capital flows into these sourcing regions through investments in mining, farming, or component manufacturing facilities. This creates a global web of suppliers, linking resource-rich areas with production centers through material and financial exchanges.

Transformation Stage
The transformation stage is where inputs are converted into finished products or sub-assemblies. This phase often involves multiple production sites spread across different countries, reflecting cost advantages, labor skills, or regulatory environments. For instance, parts might be manufactured in one country with lower labor costs, then sent to another country for assembly. Capital investment funds factories, machinery, technology, and labor required to perform these manufacturing activities. Transformation is thus a spatially fragmented process that links places through production activities and investment flows.

Distribution Stage
Once products are manufactured, they enter the distribution phase, which involves the movement of goods from production sites to markets. TNCs rely on a complex logistics network including shipping ports, airports, railways, warehouses, and retail outlets. Capital is invested in infrastructure, transport technologies, and supply chain management systems to ensure efficient and timely delivery. Distribution connects production centers to consumer markets globally, enabling products to reach a wide range of places quickly and cost-effectively.

Consumption Stage
The final component, consumption, is where products are purchased and used by end-users in different countries. Consumption patterns influence global demand and, consequently, the entire GPN. TNCs monitor these markets to adapt products to local preferences and economic conditions. Capital generated from sales flows back into the economy and is often reinvested in the production network for innovation and expansion. Through consumption, distant places become linked economically and culturally, completing the global circuit of production and capital flows.

(f) Possible responses to consider: [5]

In an increasingly globalized world, nations are connected through complex networks of trade, investment, and finance. This interdependence offers numerous benefits, including increased efficiency, access to resources, economic growth, and political cooperation. This essay explores the key advantages of economic interdependence, illustrating how it shapes global economic development and international relations.

[not for reproduce without authorisation from Temasek Junior College]

One of the fundamental benefits of economic interdependence is that it allows countries to specialize in the production of goods and services where they have a comparative advantage. According to the economic theory of comparative advantage, countries benefit by producing goods at a lower opportunity cost than others and then trading with each other. This specialization increases overall efficiency and global output. For example, countries rich in natural resources such as Saudi Arabia specialize in oil production, while countries like Germany focus on manufacturing advanced machinery. By trading, both countries benefit: Saudi Arabia receives high-quality machinery, and Germany gets access to energy supplies. This specialization results in more efficient use of global resources, increased productivity, and lower prices for consumers worldwide.

Economic interdependence also expands the variety of goods and services available to consumers beyond what domestic markets can produce. Through international trade, countries import products that are either unavailable domestically or produced more efficiently elsewhere. For instance, tropical fruits such as bananas and coffee are imported by countries in temperate climates where they cannot be grown. Similarly, countries can access advanced technologies and services from global partners, boosting consumer choice and quality of life. This access not only enhances consumer welfare but also fosters innovation. Companies are incentivized to improve their products to remain competitive in the global market, leading to continuous improvements in quality and diversity.

Economic interdependence facilitates economic growth by opening up markets for exports and enabling access to foreign direct investment (FDI). Exporting goods to international markets allows countries to scale up production, increase incomes, and create jobs. Developing countries, in particular, benefit from integrating into global value chains, where they can participate in manufacturing or assembly processes that contribute to economic development. Foreign direct investment is another critical channel through which economic interdependence promotes growth. TNCs invest capital in host countries to establish production facilities, bringing in technology, skills, and management expertise. For example, many emerging economies in Asia and Latin America have experienced rapid growth by attracting FDI in sectors such as electronics and automotive manufacturing. Moreover, economic interdependence encourages knowledge transfer and innovation diffusion. Countries can adopt new technologies and best practices from their trading partners, accelerating their development processes.

Through global trade and financial integration, countries can allocate resources more effectively and share economic risks. Economic interdependence enables countries to import goods that would be costly or inefficient to produce domestically, thereby conserving their scarce resources for more productive uses. Additionally, financial interdependence, through international capital markets, allows countries to access funds for investment, smoothing out economic cycles. When a country faces a domestic downturn, foreign investment and capital flows can help stabilize the economy. Global supply chains also spread risk by diversifying production locations. If one country experiences a disruption due to natural disasters or political instability, production can often be shifted or compensated for in other locations, maintaining supply continuity.

[not for reproduce without authorisation from Temasek Junior College]

Economic interdependence often leads to closer political ties and cooperation between countries. When nations rely on each other economically, they have greater incentives to maintain peaceful relations to protect their mutual interests. This concept is known as the "liberal peace theory," which suggests that trade and investment reduce the likelihood of conflicts by creating mutual benefits. Trade agreements and economic partnerships often form the foundation for broader diplomatic relations. Organizations such as the World Trade Organization (WTO), regional trade blocs like the European Union (EU), and bilateral trade agreements facilitate dialogue, dispute resolution, and collaborative policymaking. Economic interdependence also promotes global cooperation on shared challenges such as climate change, health pandemics, and financial crises. Countries working together economically are more likely to cooperate on these issues due to their interconnected interests.

The flow of goods and capital is often accompanied by the exchange of ideas, technologies, and cultures. Economic interdependence enables countries to benefit from innovations developed elsewhere. This technology transfer can boost productivity and lead to the creation of new industries. For example, countries participating in the global electronics supply chain have been able to absorb advanced manufacturing techniques and incorporate them into their own industries. This dynamic fosters competitiveness and economic diversification. Moreover, economic interdependence facilitates cultural exchange and understanding through business partnerships, foreign workers, and multinational corporations. This can enhance global awareness, tolerance, and collaboration beyond purely economic dimensions.

Consumers benefit directly from economic interdependence as increased trade competition tends to lower prices and improve product quality. When companies face competition from foreign producers, they have incentives to reduce costs and innovate. For example, the global textile and clothing industry allows consumers in developed countries to purchase affordable garments produced in lower-cost countries. At the same time, companies in exporting countries improve their production methods and working conditions to meet international standards. This competitive environment also promotes more sustainable production practices as consumers become increasingly aware of ethical and environmental concerns, encouraging firms to adapt accordingly.

2 (a) Possible responses to consider: [5]

- Latitudinal position
- Spatial extent of pressure zone
- Hemisphere differences
- Locational characteristics by continents
- Time of the year differences: January and July
- Location of overhead sun

(b) Possible responses to consider: [6]

The summer monsoon circulation is a dominant climatic phenomenon that profoundly influences rainfall patterns across humid tropical Asia. Characterized by

[not for reproduce without authorisation from Temasek Junior College]

a seasonal reversal of winds and a distinct wet season, the summer monsoon is essential in shaping the climate, agriculture, and livelihoods of millions in the region.

It develops due to the differential heating between the Asian continent and adjacent oceans, causing moist southwest winds to flow inland. These winds bring copious amounts of moisture, leading to widespread and often intense rainfall across the region. Orographic features such as the Western Ghats and Southeast Asian mountain ranges enhance rainfall through lifting processes, creating spatial variability. Atmospheric systems like the Tibetan Plateau low, Western Pacific high, and the monsoon trough modulate the distribution and intensity of rainfall. Moreover, global climatic factors such as ENSO influence interannual variability.

(c) Possible responses to consider: [5]

The development and path of Typhoon Haiyan were determined by a combination of favorable oceanic and atmospheric conditions. The unusually warm sea surface temperatures in the western Pacific provided the essential energy source for the storm's formation and intensification. Low vertical wind shear allowed the cyclone to organize vertically without disruption, while abundant mid-level moisture sustained deep convection and latent heat release. The monsoon trough acted as the initial breeding ground for the disturbance, and the subtropical ridge steered Haiyan westward toward the Philippines. These combined factors led to Haiyan's rapid intensification and destructive landfall, making it one of the most powerful typhoons in recorded history.

(d) Possible responses to consider:

The phases of ENSO—El Niño and La Niña—are defined by significant departures from this average state in sea surface temperatures and atmospheric circulation. These anomalies disrupt the normal climatic conditions and produce wide-ranging weather effects across the Pacific and globally. [6]

El Niño is the warm phase of ENSO and occurs when sea surface temperatures in the central and eastern equatorial Pacific become significantly warmer than average, typically by 0.5°C or more. During El Niño events, the normal east-west temperature gradient weakens or reverses. The warming of SSTs in the eastern Pacific suppresses the upwelling of cold water along the coast of South America, causing a rise in surface temperatures over a large area. This anomalous warming disrupts the atmospheric circulation by weakening or even reversing the easterly trade winds.

In contrast, La Niña is the cold phase of ENSO and occurs when sea surface temperatures in the central and eastern equatorial Pacific are significantly cooler than average. During La Niña events, the east-west SST gradient intensifies as cooler-than-normal waters dominate the eastern Pacific while the western Pacific remains warmer than average. This enhanced temperature difference strengthens the easterly trade winds, which push warm surface waters further westward and promote stronger upwelling of cold waters along the South American coast.

(e) Possible responses to consider: [4]

[not for reproduce without authorisation from Temasek Junior College]

- Shape
- Distributary network
- Vegetation and ecosystems
- Landforms within delta

(f) Possible responses to consider: [4]

The quantity and type of sediment delivered by the river are fundamental to delta formation. Rivers erode material from their drainage basins and transport sediments downstream. When the river reaches the sea or lake, the reduction in velocity causes sediment to settle and accumulate, gradually building the deltaic landform. High sediment supply generally promotes delta growth and expansion. Conversely, rivers with low sediment loads may fail to build significant deltas, especially if marine processes erode deposited material faster than it accumulates. The type of sediment also matters. Coarser sediments such as sand settle more quickly near the river mouth, forming distributary channels and levees, while finer sediments like silt and clay are carried further offshore, creating extensive floodplains and interdistributary bays. The relative proportions of sediment sizes affect delta morphology and internal stratification.

The volume and variability of river discharge significantly influence delta formation. A river with high and sustained flow can transport large sediment loads and maintain strong outflow currents that push sediments into the receiving basin. Seasonal and annual variations in discharge also matter. Rivers in monsoonal or glacial regimes often experience intense floods during certain periods, delivering pulses of sediment to the delta. On the other hand, rivers with highly regulated flow due to dams and reservoirs may deliver reduced sediment loads, slowing delta growth or causing erosion.

The delta is the interface between fluvial and marine environments, so marine processes play a crucial role in shaping its form. The relative dominance of waves, tides, and currents influences sediment distribution and delta morphology.

The topography and morphology of the receiving basin affect delta formation. A gently sloping continental shelf allows sediment to spread over a wide area, promoting delta expansion. Steep offshore gradients may limit delta progradation and favour the formation of submarine canyons instead. Sea level changes are critically important. During periods of falling sea level, deltas can rapidly prograde as rivers deposit sediment onto exposed shelves. Conversely, rising sea levels can drown deltas, causing retreat and wetland loss. The current rate of global sea level rise due to climate change threatens many low-lying deltas by increasing flooding and saltwater intrusion. Relative sea level, which considers local land subsidence and uplift, is also significant. Many deltas experience subsidence due to sediment compaction, groundwater extraction, or tectonics, exacerbating vulnerability to inundation and erosion.

Climate controls the hydrological cycle and vegetation cover in the delta and its upstream catchment, influencing sediment supply, river discharge, and erosion rates. Humid climates with abundant rainfall promote strong river flows and high sediment loads, aiding delta growth.

[not for reproduce without authorisation from Temasek Junior College]

Human interventions increasingly influence delta formation and dynamics.

QUESTION 3

Possible Approaches:

Extractive industries—those involved in the removal of natural resources such as minerals, oil, gas, coal, and metals—have played a crucial role in human civilization and economic development. From early mining in ancient times to modern-day large-scale operations, extractive industries have evolved alongside technological advances, economic systems, and geopolitical shifts. The history of extractive industries reflects humanity's evolving relationship with the Earth's resources—from ancient small-scale mining for tools to today's complex global networks of resource extraction and trade. While these industries have driven economic development and technological progress, they have also posed social and environmental challenges. Understanding their historical development provides insight into the opportunities and obstacles facing sustainable resource management in the future. Candidates could approach the question by evaluating the various environmental, social, and economic impacts of extractive industries (such as mining, oil and gas extraction, quarrying) on places, and the challenges involved in managing these impacts. Candidates could explore environmental impacts such as pollution, habitat destruction, landscape degradation, and resource depletion, alongside social impacts including displacement of communities, health issues, and changes to local livelihoods. Economic impacts might include job creation versus economic dependency or boom-bust cycles. Candidates might assess the difficulties in managing these impacts, considering factors such as conflicting stakeholder interests (government, companies, local communities), weak regulation or enforcement, technological limitations, and economic pressures to exploit resources. Candidates could evaluate different management strategies - environmental regulations, rehabilitation and reclamation projects, corporate social responsibility (CSR) initiatives, community engagement, and diversification of local economies—through relevant case studies, considering their effectiveness and limitations. Candidates might argue that while management is challenging, there are examples where impacts have been successfully mitigated or controlled, showing that management is possible but complex. Conversely, they may discuss ongoing challenges like illegal mining, corruption, or lack of resources that hamper effective management. Candidates could conclude by making a reasoned judgment on the extent to which managing impacts is difficult and the conditions that influence this difficulty.

Marking:

- Responses should demonstrate clear understanding of the range of impacts extractive industries have on places.
- High-level answers will use well-developed case studies to illustrate the challenges and management strategies.
- Candidates should critically evaluate the extent and reasons why managing impacts is difficult, rather than merely describing impacts or strategies.
- Answers should show awareness of the complexity and conflicting interests involved in management.
- Evaluation should be balanced, considering both successes and ongoing difficulties.
- A reasoned conclusion addressing the statement directly is expected.
- Use Generic Level Descriptors for 20-mark H2 essays.

QUESTION 4

Possible Approaches:

Multilateral institutions are organizations formed by three or more countries to work collaboratively on common issues that transcend national borders. These institutions play a critical role in

[not for reproduce without authorisation from Temasek Junior College]

international relations by providing frameworks for cooperation, conflict resolution, economic development, and addressing global challenges. They help to coordinate policies, set international standards, mobilize resources, and promote peace and stability. The concept of multilateralism gained prominence after World War II, driven by the desire to prevent future conflicts and promote economic recovery. The devastation of two world wars demonstrated the limits of unilateral and bilateral diplomacy, prompting the creation of institutions that could represent multiple countries and provide collective governance. Multilateral institutions remain essential for managing complex global issues in an interconnected world. By fostering cooperation, they contribute to peace, development, and sustainable solutions that no single country can achieve alone. Their continued evolution and reform will be crucial to address 21st-century challenges effectively. Candidates could approach the question by comparing the roles and influence of states versus multilateral institutions in shaping the global economy. Candidates might explore how states exercise influence through control of national economic policies, trade agreements, regulation of markets, and geopolitical power. They could evaluate how states use their economic sovereignty to protect domestic industries, negotiate bilateral trade deals, or exert economic diplomacy. Candidates could contrast this with the influence of multilateral institutions in promoting global economic governance, setting trade rules, providing financial assistance, and fostering economic cooperation and integration. They might consider the role these institutions play in shaping economic policies across multiple countries, enforcing regulations, and managing global financial stability. Candidates could analyse case studies illustrating the power dynamics between states and institutions, such as how powerful states dominate or shape multilateral agendas, or how institutions constrain state policies in pursuit of global economic goals. Candidates might also consider limitations on state power in an increasingly interconnected global economy, including economic interdependence, the role of transnational corporations, and global financial flows facilitated by multilateral frameworks. Candidates could evaluate the relative effectiveness and scope of influence of states and institutions, considering different contexts such as developed versus developing economies, or crisis versus stable periods.

Marking:

- Responses should demonstrate clear understanding of the roles and functions of states and multilateral institutions in the global economy.
- High-level answers will use relevant examples and case studies to support comparison and evaluation.
- Candidates should critically analyse the relative influence of each actor, recognising complexity and overlap.
- Answers should address both the extent and limits of influence.
- Evaluation should be balanced, showing nuanced judgment rather than a simplistic view.
- A reasoned conclusion on the statement's validity is expected.
- Use Generic Level Descriptors for 20-mark H2 essays.

QUESTION 5

Possible Approaches:

Fluvial floods occur when rivers or streams overflow their banks due to excess water. These floods are among the most common and widespread natural hazards, affecting millions of people globally each year. They can cause significant social, economic, and environmental damage, but also play important roles in shaping landscapes and ecosystems. Fluvial floods are complex natural phenomena driven by hydrological and human factors. While they pose significant risks to people and infrastructure, understanding their causes and impacts is crucial to developing effective management strategies. Embracing both natural processes and technological solutions will be essential in reducing flood vulnerability in a changing world. Candidates could approach the question

[not for reproduce without authorisation from Temasek Junior College]

by examining how the impacts of fluvial floods vary across different social groups and geographical locations. They might consider physical factors such as flood magnitude, frequency, duration, and the characteristics of the affected landscape (urban vs rural, developed vs developing regions). Candidates could analyse the differential vulnerability of people, considering socio-economic status, housing quality, access to resources, and preparedness. For example, poorer communities may suffer greater loss and slower recovery compared to wealthier groups. Candidates could evaluate how place-specific factors such as land use, floodplain management, and local governance influence the scale and severity of flood impacts. Urban areas might face issues such as infrastructure damage and economic disruption, while rural areas might experience agricultural losses and displacement. Candidates could use case studies to illustrate variations in impact, recovery, and response strategies, highlighting contrasts between countries or regions with differing levels of development and flood management capacity. Candidates might also discuss how cultural, political, and economic contexts affect resilience and recovery, and the role of external aid or insurance in mitigating impacts. Candidates could conclude by assessing the extent of differences in flood impacts, recognising both common patterns and significant variations.

Marking:

- Responses should demonstrate clear understanding of the physical and human factors influencing flood impacts.
- High-level answers will include detailed, relevant case studies to illustrate differential effects on people and places.
- Candidates should critically analyse reasons for variation rather than merely describing impacts.
- Evaluation should consider multiple dimensions—social, economic, environmental, and spatial.
- Answers should be balanced, showing awareness of complexity and nuance in flood impacts.
- A reasoned conclusion addressing the degree of difference in flood effects is expected.
- Use Generic Level Descriptors for 20-mark H2 essays.

QUESTION 6

Possible Approaches:

Karst landscapes are among the most striking and unique natural environments on Earth, renowned for their dramatic scenery and fascinating geological features. Formed primarily through the dissolution of soluble rocks such as limestone, dolomite, and gypsum, karst regions are characterized by distinctive landforms including caves, sinkholes, underground rivers, and towering limestone pinnacles. Their aesthetic appeal lies not only in their physical grandeur but also in the rich interplay of geology, hydrology, and ecology that creates a landscape both mysterious and enchanting. One of the most captivating aspects of karst landscapes is the variety of dramatic landforms they present. Towering limestone cliffs and steep karst towers, often seen in places like Guilin in China or Ha Long Bay in Vietnam, rise sharply from relatively flat plains or water bodies. These karst towers are sculpted over millions of years by chemical weathering and erosion, creating jagged, almost otherworldly shapes that inspire awe. Candidates could approach the question by assessing the extent to which karst landforms in humid tropical environments are shaped exclusively by geomorphic processes. Candidates might describe key geomorphic processes involved in karst formation—chemical weathering, underground drainage development, sinkhole formation, and cave development—especially in the context of high rainfall and warm temperatures in the humid tropics. Candidates could evaluate the role of other factors beyond purely geomorphic processes, such as the influence of biological activity (e.g., vegetation enhancing chemical weathering), human activities (land use, deforestation, agriculture), and climatic variability. Candidates might consider the

[not for reproduce without authorisation from Temasek Junior College]

contribution of tectonic activity in shaping the initial landscape (uplift, fracturing of rock) which enables karst processes to operate, thus challenging the idea that karst landforms are solely due to geomorphic processes. Case studies from karst regions in the humid tropics (e.g., parts of Southeast Asia, the Caribbean, Central America) could be used to illustrate how geomorphic and non-geomorphic factors interact. Candidates could weigh the extent to which geomorphic processes dominate compared to other influences, concluding whether it is accurate to describe karst landforms as solely the result of geomorphic processes.

Marking:

- Responses should show clear understanding of karst geomorphology and the processes driving karst landform development.
- High-level answers will include relevant case studies from humid tropical environments.
- Candidates should critically evaluate the statement, considering the role of both geomorphic and non-geomorphic factors.
- Answers should demonstrate awareness of complexity and interaction between natural and human influences.
- A balanced evaluation with a reasoned judgment on the statement's validity is expected.
- Use Generic Level Descriptors for 20-mark H2 essays.

Reminder of essay level descriptors

Levels	Marks	Generic Level Descriptors for H2 Essays
5	18–20	Evaluation is consistently analytical and coherent. Response is well-supported by relevant material, including the effective use of examples. Response features accurate geographical knowledge and reflects good understanding of the subject content relevant to the question.
4	14–17	Evaluation is analytical and coherent. Response is mostly well-supported by relevant material, including the appropriate use of examples. Response features accurate geographical knowledge and reflects adequate understanding of the subject content relevant to the question.
3	10–13	Evaluation is broadly analytical and generally coherent. Response is moderately well-supported by relevant material, including some appropriate use of examples. Response features accurate geographical knowledge and reflects adequate understanding of the subject content relevant to the question.
2	6–9	Response is largely descriptive with limited analysis and evaluation. Response is partly coherent and may lack clarity in parts. Response is poorly supported by relevant materials, including the limited use of examples. Response features inaccurate geographical knowledge and poor understanding of the subject content relevant to the question.
1	1–5	Response is descriptive with no analysis or evaluation. Response is fragmented and lacks clarity. Response consists of unsupported assertions. Response features largely inaccurate geographical knowledge and a lack of understanding of the subject content relevant to the question.
0	0	No creditworthy response

[not for reproduce without authorisation from Temasek Junior College]
